19 Compressive forces are applied normally to the end faces of a cylinder of initial length *L*. The cylinder is compressed by the forces so that its length decreases to 0.6*L*. After the compressive forces are removed, the cylinder's length increases to 0.8*L*.

What describes the deformation of the cylinder when its length was 0.6*L*?

A both elastic and plastic

B elastic only

C plastic only

D neither elastic nor plastic
